Spontaneous Processes

The first law of thermodynamics states that **if** a reaction takes place, the total energy of the universe remains unchanged.

However, the first law does not address the questions that lies behind the "**if**".

- Why do some reactions have a *tendency* to occur?
- Why does a reaction even happen?

Spontaneous Change

If **no external influence drives a change** (e.g., no work done on the system) the change is **spontaneous**.

Examples:

- A hot block of metal spontaneously cools to the temperature of its surroundings, while the reverse process does not occur.
- A gas expands spontaneously into another evacuated flask, but the reverse process does not occur.

Nonspontaneous Change

Changes can be *made to happen* in an "unnatural" direction.

- We can force an electric current through a block of metal to heat it to a higher temperature
- We can drive a gas into a smaller volume by pushing it with a piston.

These are examples of a *nonspontaneous change*: we have to force them to happen; a nonspontaneous change is done with **work**.

-
- We can conclude that a spontaneous process has a direction.
 - A process that is spontaneous in one direction is *nonspontaneous* in the opposite direction.
 - Temperature may also affect the spontaneity of a process.

Reversible Processes

A **reversible process** is one that can go back and forth between states along the same path.

- The reverse process restores the system to its original state.
- The path taken back to the original state is *exactly* the reverse of the forward process.
- There is no net change in the system or the surroundings when this cycle is completed.

- Completely reversible processes are too slow to be attained in practice.
- For a system at equilibrium, reactants and products can interconvert *reversibly*.

Consider the interconversion of ice and water at 1 atm, 0 °C.

- We now add heat to the system from the surroundings.
 - We melt 1 mole of ice to form 1 mole of liquid water.
 - * $q = \Delta H_{fus}$

To return to the original state, we reverse the procedure.

- We remove the same amount of heat from the system to the surroundings.
- Ice and water are in equilibrium

Irreversible Processes

A **irreversible process** cannot be reversed to restore the system and surroundings back to their original state.

- A different path (with different values of q and w) must be taken.
- Consider a gas in a cylinder with a piston.
 - Remove the partition, and the gas expands to fill the space.
 - No P-V work is done on the surroundings.
 - * $w = 0$
 - Now use the piston to compress the gas back to the original state.
 - The surroundings must do work on the system.
 - * $w > 0$
- A different path is required to get the system back to its original state.
- Note that the surroundings are NOT returned to their original conditions.
- For a spontaneous process, the path between reactants and products is *irreversible*.

Entropy and Disorder

The **natural progression** of a system and its surroundings is from **order to disorder**, from **lower to higher entropy**.

To quantify entropy we take a thermally insulated, sealed flask or a calorimeter, to measure and make precise predictions about disorder.

A entropy change in a system is calculated as:

$$\Delta S = \frac{q_{rev}}{T}$$

q is energy transferred, "rev" means energy must be transferred reversibly, **infinitesimal change**, T is the absolute temperature, and the typical units for entropy are $J \cdot K^{-1}$.

A Molecular Statistical Interpretation of Entropy

- *Statistical thermodynamics* is a field that uses statistics and probability to link the microscopic and macroscopic worlds.
 - Entropy may be connected to the behavior of atoms and molecules.
 - Envision a **microstate**: a snapshot of the positions and speeds of all molecules in a sample of a particular macroscopic state at a given point in time.
 - Consider a molecule of ideal gas at a given temperature and volume.
 - * A microstate is a single possible arrangement of the positions and kinetic energies of the gas molecules.
 - * Other snapshots are possible (different microstates).
 - Each thermodynamic state has a characteristic number of microstates (Ω)

The Boltzmann equation shows how entropy (S) relates to Ω .

$$S = k_B \ln \Omega$$

where k_B is Boltzmann's constant ($1.38 \times 10^{-23} J/K$).

Entropy is thus a measure of how many microstates are associated with a particular macroscopic state.

- Any change in the system that increases the number of microstates gives a positive value of ΔS and vice versa.
- In general, the number of microstates will increase with an increase in volume, and increase in temperature, or an increase in the number of molecules because any of these changes increases the possible positions and energies of the molecules.

Making Qualitative Predictions About ΔS

- In most cases, an increase in the microstates (and thus entropy) parallels an increase in:
 - temperature
 - volume
 - number of independently moving particles.
- Consider the melting of ice.
 - In ice, the molecules are held rigidly in a lattice.
 - When it melts, the molecules will have more freedom to move (increases the number of degrees of freedom).
 - The molecules are more randomly distributed.
- Consider a KCl crystal dissolving in water.
 - The solid KCl has ions in a highly ordered arrangement.
 - When the crystal dissolves, the ions have more freedom.
 - They are more randomly distributed.
 - However, now the water molecules are more ordered.
 - Some must be used to hydrate the ions.
 - * Thus this example involves both ordering and disordering.
 - * The disordering usually predominates (for most salts).
 - * Some salts do not dissolve in water (e.g., AgCl_2) because the ordering dominates.

- Consider the reaction of $\text{NO}(g)$ with $\text{O}_2(g)$ to form $\text{NO}_2(g)$:

- The total number of gas molecules decreases.
 - * Therefore, the entropy decreases.
- How can we relate changes in entropy to changes at the molecular level?
 - Formation of the new N-O bonds "tie up" more of the atoms in the products than in the reactants.
 - The *degrees of freedom* associated with the atoms have changed.
 - The greater the freedom of movement and degrees of freedom, the greater the entropy of the system.
 - Individual molecules have degrees of freedom associated with motions within the molecule.
- In general, entropy will increase when:
 - Liquids or solutions are formed from solids
 - Gases are formed from solids or liquids
 - The number of gas molecules increases.

The Second Law of Thermodynamics

The Entropy of the universe (i.e., the disorder in the world), never decreases; more precisely: entropy increases if there are irreversible processes and stays constant for reversible processes.

- Entropy can be created but not destroyed.
- Entropy need not be conserved.

Definition of Entropy

$$\Delta S = S_f - S_i = \int_i^f \frac{dq_{rev}}{T}$$

- Identify initial and final states
- Select any convenient reversible path
- Evaluate the integral

Entropy Changes of Reversible Processes

1. ΔS_{sys} for Isothermal Processes: **T is constant.**

$$\Delta S = \int_i^f \frac{dq_{rev}}{T} = \frac{1}{T} \int_i^f dq_{rev} = \frac{q_{rev}}{T}$$

$$\Delta S = \frac{q_{rev}}{T}$$

- (a) **Compression/Expansion** of an Ideal Gas:

$$q_{rev} = nRT \ln \left(\frac{V_2}{V_1} \right)$$

$$\Delta S = nR \ln \left(\frac{V_2}{V_1} \right) \quad (\text{with constant T})$$

- Entropy of a gas increases during isothermal expansion $V_2 > V_1$

(b) **Phase Transition:** melting a solid at constant pressure

$$q_{rev} = q_p = \Delta H_{fus}$$

$$\Delta S = \frac{q_{rev}}{T_{fus}} = \frac{\Delta H_{fus}}{T_{fus}}$$

- The entropy increases when a solid melts.

2. ΔS_{sys} for Processes with Changing Temperature

$$\Delta S = \int_i^f \frac{dq_{rev}}{T}$$

(a) Reverse Isochoric Process: Constant Volume

$$dq_{rev} = n \cdot c_v dT$$

$$\Delta S = \int_{T_1}^{T_2} \frac{dq_{rev}}{T} = \int_{T_1}^{T_2} \frac{n \cdot c_v dT}{T} = n \cdot c_v \int_{T_1}^{T_2} \frac{dT}{T} = n \cdot c_v \ln \left(\frac{T_2}{T_1} \right)$$

(b) Reverse Isobaric Process: Constant Pressure

$$dq_{rev} = n \cdot c_p dT$$

$$\Delta S = \int_{T_1}^{T_2} \frac{dq_{rev}}{T} = \int_{T_1}^{T_2} \frac{n \cdot c_p dT}{T} = n \cdot c_p \int_{T_1}^{T_2} \frac{dT}{T} = n \cdot c_p \ln \left(\frac{T_2}{T_1} \right)$$

3. ΔS for Surrounding: Heat gained by surroundings is the heat lost by the system.

$$q_{surr} = -q_{sys}$$

- At constant P:

$$q_{surr} = -\Delta H_{sys}$$

$$\Delta S_{surr} = \frac{-\Delta H_{sys}}{T_{surr}}$$

- The heat capacity of the surroundings is large: Heat transferred doesn't change **temperature**.

Entropy Changes and Spontaneity

A process can occur **spontaneously** if the total entropy change for the thermodynamic universe of the process is positive:

$$\Delta S_{univ} = \Delta S_{sys} + \Delta S_{surr} > 0$$

For reversible processes:

$$\Delta S_{univ} = \Delta S_{sys} + \Delta S_{surr} = 0$$

Entropy is not conserved: ΔS_{univ} is continually increasing.

The Third Law of Thermodynamics

The entropy of any pure substance (element or compound) in its equilibrium state approaches zero at the absolute zero of temperature.

Standard-State Entropies

$$\Delta S = n \int_{T_1}^{T_2} \frac{c_p}{T} dT$$

S_T , absolute entropy of 1 mole of substance at temperature T

$$S_T = \int_0^T \frac{c_p}{T} dT$$

Standard molar entropy

$$S^\circ = \int_0^{298.15} \frac{c_p}{T} dT + \Delta S \quad (\text{phase changes between 0 and 298.15K})$$

The Gibbs Free Energy

$$\Delta S_{tot} = \Delta S_{sys} + \Delta S_{surr}$$

- $\Delta S_{tot} > 0$: spontaneous
- $\Delta S_{tot} = 0$: reversible
- $\Delta S_{tot} < 0$: nonspontaneous

The Nature of Spontaneous Processes at Fixed T and P

$$\begin{aligned} \Delta S_{surr} &= \frac{-\Delta H_{sys}}{T_{surr}} \\ \Delta S_{tot} = \Delta S_{sys} + \Delta S_{surr} &= \Delta S_{sys} - \frac{\Delta H_{sys}}{T_{surr}} = \frac{-(\Delta H_{sys} - T_{surr} \Delta S_{sys})}{T_{surr}} \\ T_{surr} = T_{sys} &= T \\ \Delta S_{tot} &= \frac{-(\Delta H_{sys} - T \Delta S_{sys})}{T} \end{aligned}$$

Gibbs Free Energy Formula

We define the Gibbs Free Energy G :

$$\begin{aligned} G &= H - TS \\ \Delta S_{tot} &= \frac{-\Delta G_{sys}}{T} \end{aligned}$$

- $\Delta G_{sys} > 0$: nonspontaneous processes
- $\Delta G_{sys} = 0$: reversible processes
- $\Delta G_{sys} < 0$: spontaneous processes

Gibbs Free Energy and Phase Transitions

The standard molar Gibbs free energy of formation: ΔG_f° is the change in Gibbs free energy for the reaction in which 1 mole of the compound in its standard state is formed from its elements in their standard states.

$$\Delta G = \Delta H - T \Delta S$$

Effects of Temperature on ΔG

$$\begin{aligned} \Delta G^\circ &= \Delta H^\circ - T \Delta S^\circ \\ T^\circ &= \frac{\Delta H^\circ}{\Delta S^\circ} \end{aligned}$$
